大树下玩耍

OpenSSL.Net使用随记(二)

前面已经把使用OpenSSL.Net环境准备好了,现在来调用几个常用算法的实现

MD5, SHA1

在这只需要注意下OpenSSL.Crypto.MessageDiges后面签名算法会用到。

```
1
       class Program_Hash
 2
 3
           static void Main(string[] args)
               var ciphertext = MD5("Md5加密。", Encoding.UTF8);
 5
 6
               ciphertext = SHA1("SHA1加密。", Encoding.UTF8);
 8
 9
           public static string MD5(string text, Encoding encoding)
10
               return HashDigest(text, encoding, MessageDigest.MD5);
11
13
14
           public static string SHA1 (string text, Encoding encoding)
15
16
               return HashDigest(text, encoding, MessageDigest.SHA1)
18
19
           private static string HashDigest(string text, Encoding er
21
               using (MessageDigestContext hashDigest = new MessageI
22
23
                   byte[] hashBytes = encoding.GetBytes(text);
24
                   byte[] signByte = hashDigest.Digest(hashBytes);
                   return BitConverter.ToString(signByte).Replace("-
26
27
28
- 4 |
```

AES

- 1、在这里SymmetricCrypt是之前项目封装的 System.Security.Cryptography.RijndaelManaged
 - 2、Key与IV是有其规律的因此IV是可以去掉
- 3、在string与byte[]之间转换时要注意编码,什么时候用Convert.FromBase64String,什么时候用Encoding

4、可以查看下Cipher封装,里面有不同的算法

```
1
      class Program Symmetric
 2
 3
           static void Main(string[] args)
 4
               SymmetricCrypt symmetric = new SymmetricCrypt(CryptT)
               string key = "PGKQBXNCiuwKmlIUThSy1h+ZHMAN+HytbZny/Fe
                  iv = "aqauVvyO7qvAbaDsdOeFsA==",
 8
                   text = "AES256加解密。";
 9
10
               var ctext = symmetric.Encrypt(text, key, iv);
11
12
               var ctext2 = symmetric.Decrypt(ctext, key, iv);
13
14
               var ctext3 = Encrypt(ctext2, key, iv);
15
               Decrypt(ctext3, key, iv);
17
           }
18
19
           public static string Decrypt(string text, string key, str
20
21
               byte[] keyBytes = Convert.FromBase64String(key);
22
               byte[] ivBytes = Convert.FromBase64String(iv);
23
               byte[] textBytes = Convert.FromBase64String(text);
24
               using (CipherContext cipher = new CipherContext(Ciphe
25
26
                   byte[] output = cipher.Decrypt(textBytes, keyByte
                   var result = Encoding.UTF8.GetString(output);
                   return result;
28
29
30
31
32
           public static string Encrypt(string text, string key, st;
33
34
               byte[] keyBytes = Convert.FromBase64String(key);
35
               byte[] ivBytes = Convert.FromBase64String(iv);
36
               byte[] textBytes = Encoding.UTF8.GetBytes(text);
37
               using (CipherContext cipher = new CipherContext(Ciph€
39
                   byte[] output = cipher.Encrypt(textBytes, keyByte
                   var result = Convert.ToBase64String(output);
40
41
                   return result;
43
44
→
```

RSA

- 1、公钥与私钥可以用OpenSSL命令行随意生成
- 2、OpenSSL.Core.BIO简单理解是用于装载密钥的容器
- 3、注意OpenSSL.Crypto.RSA的静态方法

Powered by: 博客园 Copyright © 2021 Azeri Powered by .NET 5.0 on Kubernetes

4、OpenSSL.Crypto.CryptoKey用于装载BIO能把密钥转换成具体的算法对

象,这个类的作用很大,涉及到签名验签都会用到

```
1 class Program RSA
           static void Main(string[] args)
               string privateKey = "", publicKey = "", text = "RSA-
                int padding = 1;
               Encoding encoding = Encoding.UTF8;
               using (RSA rsa = new RSA())
 8
10
                    rsa.GenerateKeys(1024, BigNumber.One, null, null
                    privateKey = rsa.PrivateKeyAsPEM;
11
12
                    publicKey = rsa.PublicKeyAsPEM;
13
14
15
               ctext = PrivateEncrypt(privateKey, text, encoding, r
16
               text = PublicDecrypt (publicKey, ctext, encoding, page
               ctext = PublicEncrypt(publicKey, text, encoding, pag
18
19
               text = PrivateDecrypt(privateKey, ctext, encoding, ;
21
               var signText = Sign(privateKey, text, encoding);
22
                var signTag = Verify(publicKey, text, signText, enco
